Abstract. Accurate and consistent satellite-based precipitation estimates blended with rain gauge data are important for regional precipitation monitoring and hydrological applications, especially in regions with limited rain gauges. However, existing fusion precipitation estimates often have large uncertainties over mountainous areas with complex topography and sparse rain gauges, and the existing data blending algorithms are very bad at removing the day-by-day random errors. Therefore, the development of effective methods for high-accuracy precipitation estimates over complex terrain and on a daily scale is of vital importance for mountainous hydrological applications. This study aims to offer a novel approach for blending daily precipitation gauge data and the Climate Hazards Group Infrared Precipitation (CHIRP, daily, 0.05°) satellite-derived precipitation developed by the UC Santa Barbara over the Jinsha River Basin for the period of June-July-August from 1994 to 2014. This method is named the Wuhan University Satellite and Gauge precipitation Collaborated Correction (WHU-SGCC). The results show that the WHU-SGCC method is effective in liquid precipitation bias adjustments from point to surface, which is evaluated by multiple error statistics and from different perspectives. Moreover, the accuracy of the spatial distribution of the precipitation estimates derived from the WHU-SGCC method is related to the complexity of the topography. The validation also verifies that the proposed approach is effective in the detection of the major precipitation events inside the Jinsha River Basin with the daily precipitation less than 25 mm. This study indicates that the WHU-SGCC approach is a promising tool to monitor monsoon precipitation over the Jinsha River Basin, the complicated mountainous terrain with sparse rain gauge data, considering the spatial correlation and the historical precipitation characteristics. The daily precipitation estimations at 0.05° resolution over the Jinsha River Basin during the summer seasons from 1990 to 2014, derived from WHU-SGCC are available at the PANGAEA Data Publisher for Earth & Environmental Science portal (https://doi.pangaea.de/10.1594/PANGAEA.896615)

1 Introduction

Accurate and consistent estimates of precipitation are vital for hydrological modelling, flood forecasting and climatological studies in support of better planning and decision making (Agutu et al., 2017;Cattani et al., 2018;Roy et al., 2017). In general, ground-based gauge networks include a substantial number of liquid precipitation observations measured with high accuracy, high temporal resolution, and long historical records. However, sparse distribution and point measurements limit the accurate estimation of spatially gridded rainfall (Martens et al., 2013).

Due to the sparseness of rain gauges and their uneven spatial distribution and high proportion of missing data, satellite-derived precipitation data are an attractive supplement offering the advantage of plentiful information with high spatio-temporal resolution over widespread regions, particularly over oceans, high elevation mountainous regions, and other remote regions where gauge networks are difficult to deploy. However, satellite estimates are susceptible to systematic biases that can influence hydrological modelling and the retrieval algorithms are relatively insensitive to light rainfall events, especially in complex terrain, resulting in underestimation of the magnitude of precipitation events (Behrangi et al., 2014;Thiemig et al., 2013;Yang et al., 2017). Without adjustments, inaccurate satellite-based precipitation estimates will lead to unreliable

assessments of risk and reliability (AghaKouchak et al., 2011).

Accordingly, there are many kinds of precipitation estimates combining multiple sources datasets. Since 1997, the Tropical Rainfall Measurement Mission (TRMM) has improved satellite-based rainfall retrievals over tropical regions (Kummerow et al., 1998;Simpson et al., 1988), and then applies a stepwise method for blending daily TRMM Multisatellite Precipitation Analysis (TMPA) output with rain gauges in South America (Vila et al., 2009). The Global Precipitation Measurement (GPM) satellite was launched after the success of the TRMM satellite by the cooperation of National Aeronautics and Space Administration (NASA) and Japan Aerospace Exploration Agency (JAXA) on February 27, 2014 (Mahmoud et al., 2018;Ning et al., 2016). The main core observatory satellite (GPM) cooperates with the ten other satellites (partners) to offer the high spatiotemporal resolution products (0.1° × 0.1°- half- hourly) of the global real-time precipitation estimates (Mahmoud et al., 2019). The Geostationary Operational Environmental Satellite (GOES)-R Series is the geostationary weather satellites, which significantly improves the detection and observation of environmental phenomena. The Advanced Baseline Imager (ABI) onboard the GOES-R platform will provide images in 16 spectral bands, spatial resolution of 0.5 to 2 km (2 km in the infrared and 1–0.5 km in the visible), and full-disk scanning every 5 minutes over the continental United States. The GOES-R Series will offer the enhanced capabilities for satellite-based rainfall estimation and nowcasting (Behrangi et al., 2009;Schmit et al., 2005). The Global Precipitation Climatology Project (GPCP) is one of the successful projects for blending rain gauge analysis and multiple satellite-based precipitation estimates, and constructed a relatively coarse-resolution (monthly, 2.5° × 2.5°) global precipitation dataset (Adler et al., 2003;Huffman et al., 1997). To improve the resolution of this satellite-based dataset, the GPCC network data was incorporated into remote sensing information with Artificial Neural Networks (PERSIANN) rainfall estimates, which provides finer temporal and spatial resolutions (daily, 0.25° × 0.25°) (Ashouri et al., 2015). The CPC Merged Analysis of Precipitation (CMAP) product is a data blending and fusion analysis of gauge data and satellite-based precipitation estimates (Xie and Arkin, 1996). CMAP has a long-term dataset series from 1979, while the resolution is relatively coarse. Although the aforementioned products are widely used and have performed well, the data resolution cannot achieve high accuracy in precipitation monitoring over the Jinsha River Basin, China.

Currently, the Climate Hazards Group Infrared Precipitation with Station data (CHIRPS) developed by the UC Santa Barbara, which has a higher spatial resolution (0.05°), can solve the scale problem. CHIRPS is a long-term precipitation data series, which merges three types of information: global climatology, satellite estimates and in situ observations. Table 1 shows the temporal and spatial resolution of current major satellite-based precipitation datasets. The CHIRPS precipitation dataset with several temporal and spatial scales has been evaluated in Brazil (Nogueira et al., 2018;Paredes-Trejo et al., 2017), Chile (Yang et al., 2016;Zambrano-Bigiarini et al., 2017), China (Bai et al., 2018), Cyprus (Katsanos et al., 2016b;Katsanos et al., 2016a), India (Ali and Mishra, 2017) and Italy (Duan et al., 2016). Nevertheless, the temporal resolutions of the aforementioned applications were mainly at seasonal and monthly scales, lacking the evaluation of daily precipitation. Additionally, despite the great potential of gauge-satellite fusing products for large-scale environmental monitoring, there are still large discrepancies with ground observations at the sub-regional level where these data are applied. Furthermore, the CHIRPS product reliability has not been analysed in detail for the Jinsha River Basin, China, particularly on a daily scale. The existing research indicates that estimations over mountainous areas with complex topography often have large uncertainties and systematic errors due to the topography, seasonality, climate impact and sparseness of rain gauges (Derin et al., 2016;Maggioni and Massari, 2018;Zambrano-Bigiarini et al., 2017) Moreover, Bai et al., 2018 evaluates CHIRPS over mainland China and indicates that the performance of CHIRPS is poor over the Sichuan Basin and the Northern China Plain, which have complex terrains with substantial variations in elevation. Additionally, Trejo et al., 2016 shows that CHIRPS overestimates low monthly rainfall and underestimates high monthly rainfall using several numerical metrics, and rainfall event frequency is overestimated excluding the rainy season.

Table 1 Coverage and spatiotemporal resolutions of major satellite precipitation datasets

Product	Temporal resolution	Spatial resolution	Period	Coverage
TRMM 3B42	3hours	0.25°	1998-present	50°S-50°N
GPM	30min/Hourly/ 3hours/Daily/3Day/7 Day/Monthly	0.1°/0.25°/0.05°/5°	2014-present	60°S-60°N 70°N-70°S 90°N-90°S
GOES-R	5min/15min	0.5-2 km	2016-present	the continental United States/ western hemisphere
GPCP	Monthly/Pentad	2.5°	1979-(delayed) present	90°S-90°N
PERSIANN-CDR	Daily	0.25°	1983-(delayed) present	60°S-60°N
CMAP	Monthly	2.5°	1979- present	90°S-90°N
CHIRPS	Annual/Monthly/ Dekad/Pentad/Daily	0.05°/0.25°	1981- present	50°S-50°N

To overcome these limitations, many studies have focused on proposing effective methodologies for blending rain gauge observations and satellite-based precipitation estimates, and sometimes radar data to take advantage of each dataset. Many numerical models are established among these datasets for high-accuracy precipitation estimations, such as bias adjustment by a quantile mapping (QM) approach (Yang et al., 2016), Bayesian kriging (BK) (Verdin et al., 2015) and a conditional merging technique (Berndt et al., 2014). Among aforementioned methods, the QM approach is a distribution-based approach, which works with historical data for bias adjustment and is effective in reducing the systematic bias of regional climate model precipitation estimates at monthly or seasonal scales (Chen et al., 2013). However, the QM approach offers very limited improvement in removing day-by-day random errors. The BK approach shows very good model fit with precipitation observations. Unfortunately, the Gaussian assumption of the BK model is invalid for daily scales. Overall, there is a lack of effective methods for high-accuracy precipitation estimates over complex terrain on a daily scale.

As such, due to the poor performance of CHIRPS data at the sub-regional scale and the shortcomings of the existing blending algorithms, the aim of this article is to offer a novel approach for blending daily liquid precipitation gauge data and the Climate Hazards Group Infrared Precipitation (CHIRP) satellite-derived precipitation estimates developed by the UC Santa Barbara, over the Jinsha River Basin. Here, we will use precipitation to name liquid precipitation throughout the text. The CHIRP is the raw data of CHIRPS before blending in rain gauge data. The objective is to build corresponding precipitation models that consider terrain factors and precipitation characteristics to produce high-quality precipitation estimates. This novel method is named the Wuhan University Satellite and Gauge precipitation Collaborated Correction (WHU-SGCC) method. We demonstrate this method by applying it to daily precipitation over the Jinsha River Basin during the summer seasons from 1990 to 2014. The results support the validity of the proposed approach for producing refined satellite-gauge precipitation estimates over mountainous areas.
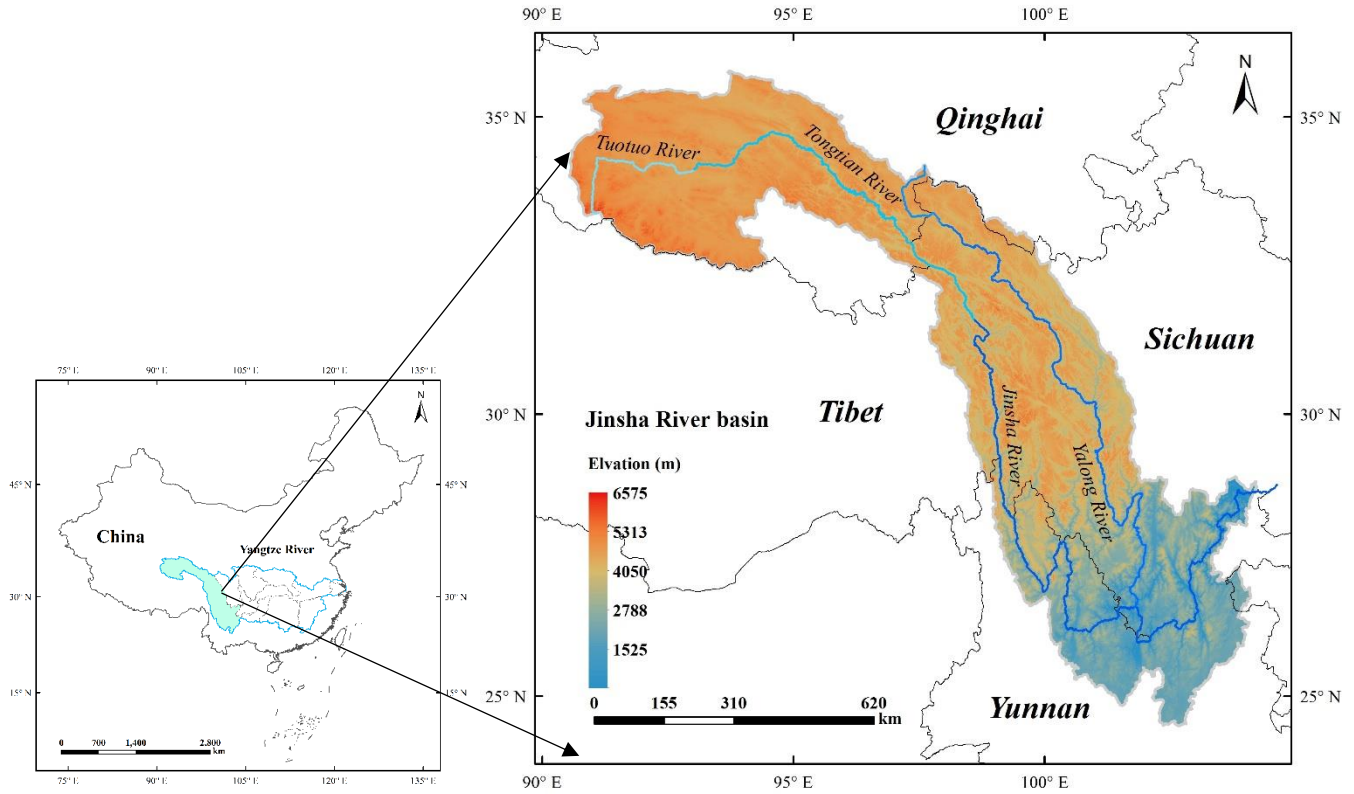

The remainder of this paper is organized as follows: Section 2 describes the study region and rain gauges and CHIRPS dataset used in this study. Section 3 presents the principle of the WHU-SGCC approach for high-accuracy precipitation estimates. The results and discussion are analysed in Section 4, and conclusions and future work are presented in Section 5.

2 Study Region and Data

2.1 Study Region

The Yangtze River, one of the largest and most important rivers in Southeast Asia, originates on the Tibetan Plateau and extends approximately 6300 km eastward to the East China Sea. The river's catchment proximately covers an area of approximately ~180 × 10^4 km^2 and the average annual precipitation is approximately 1100 mm (Zhang et al., 2019).Yangtze River is divided into nine sub-basins, the upper drainage basin is the Jinsha River Basin, which flows through the provinces of Qinghai, Sichuan, and Yunnan in western China. The total river length is 3486 km, accounting for 77% of the length of the upper Yangtze River, and covering a watershed area of 460 × 10^3 km^2. The location of the Jinsha River Basin is shown in Fig. 1, and covers the

eastern part of the Tibetan Plateau and the part of the Hengduan Mountains. The southern portion of the river basin is the Northern Yunnan Plateau and the eastern portion includes a wide area of the southwestern margin of the Sichuan basin. Crossing complex and varied terrains, the elevation of the Jinsha River ranges from 263 to 6575 m above sea level, which results in significant temporal and spatial weather variation within the basin. The average annual precipitation of the Jinsha River Basin is approximately 710 mm, the average annual precipitation of the lower reaches is approximately 900-1300 mm, while the average annual precipitation of the middle and upper reaches is approximately 600-800 mm (Yuan et al., 2018). The climate of the Jinsha River Basin has more precipitation during the summer season (June-July-August, JJA), which is affected by oceanic southwest and southeast monsoons. Therefore, the blending of satellite estimations with gauged observations during the JJA is the main focus of this research.

Figure 1 Location of the study area with key topographic features.

2.2 Study Data

### 2.2.1 Precipitation gauge observations

Daily rain gauge observations at 30 national standard rain stations in the Jinsha River Basin during the JJA from 1990 to 2014 were provided by the National Climate Centre (NCC) of the China Meteorological Administration (CMA) （http://data.cma.cn/data/cdcdetail/dataCode/SURF_CLI_CHN_MUL_DAY_V3.0.html, last access: 10 December, 2018）, which imposes a strict quality control at station-provincial-state levels. Station identification numbers and relevant geographical characteristics are shown in Table 2, and their uneven spatial distribution is shown in Fig. 2. The selected rain gauges are located in Qinghai, Tibet, Sichuan and Yunnan Provinces but are mainly scattered in Sichuan Province, and the number of rain gauges in the northern river basin is less than in the southern river basin. In this study, the gauge observations were used as the reference data in bias adjustment of satellite precipitation estimations.

138

Table 2 Geographical characteristics of rain stations.

Station number	Province	Lat (°N)	Lon (°E)	Elevation (m)
52908	Qinghai	35.13	93.05	4823
56004	Qinghai	34.13	92.26	4744

139   The multi-year (1990-2014) average annual precipitation during the JJA over the Jinsha River Basin increases from north

140   to south (Fig. 2). The spatial distribution of precipitation is uneven, with an average annual precipitation ranging from less

141   than 250 mm to more than 600 mm during the summer seasons.

142

143 **Figure 2** The multi-year (1990-2014) average annual precipitation during JJA over the Jinsha River Basin. 30 rain stations were provided
144 by the China Meteorological Administration stations, the other 18 CHIRPS fusion stations were provided by the Climate Hazards Group UC
145 Santa Barbara online at ftp://ftp.chg.ucsb.edu/pub/org/chg/products/CHIRPS-2.0/diagnostics/global_monthly_station_density/tifs/p05/ (last

146 access: 10 December, 2018).

2.2.2 CHIRPS satellite-gauge fusion precipitation estimates

148 The CHIRPS v.2 dataset, a satellite-based daily rainfall product, is available online at
149 ftp://ftp.chg.ucsb.edu/pub/org/chg/products/CHIRPS-2.0/global_daily/tifs/p05/ (last access: 10 December, 2018). It covers a
150 quasi-global area (land only, 50° S-50° N) with several temporal scales (daily, 3-day, 6-day or monthly time steps) and high
151 spatial resolution (0.05°) (Rivera et al., 2018). This dataset contains a wide variety of satellite-based rainfall products derived
152 from multiple data sources and incorporates four data types: monthly precipitation from CHPClim v.1.0 (Climate Hazards
153 Group's Precipitation Climatology version 1) derived from the combination of the satellite fields, gridded physiographic
154 indicators, and in situ climate normal with the geospatial modelling approach based on moving window regressions and inverse
155 distance weighting interpolation (Funk et al., 2015 b), quasi-global geostationary thermal infrared satellite observations
156 (TRMM 3B42 version 7), atmospheric model rainfall fields CFS (Climate Forecast System) from NOAA, and surface based
157 precipitation observations from various sources including national or regional meteorological services. The differences from
158 other frequently used precipitation products are the higher resolution of 0.05° and the longer-term data series from 1981 to the
159 present (Funk et al., 2015 a).

160 CHIRPS is the blended product of a two-part process. First, IR precipitation (IRP) pentad rainfall estimates are fused with
161 corresponding CHPClim pentad data to produce an unbiased gridded estimate, called the Climate Hazards Group IR
162 Precipitation (CHIRP), which is available online at ftp://ftp.chg.ucsb.edu/pub/org/chg/products/CHIRP/daily/ (last access: 10
163 December, 2018). In the second part of the process, CHIRP data is blended with in situ precipitation observations obtained
164 from a variety of sources including national and regional meteorological services by means of a modified inverse-distance
165 weighting algorithm to create the final blended product, CHIRPS (Funk et al., 2014). The daily CHIRP satellite-based data
166 over the Jinsha River Basin during the summer seasons from 1990 to 2014 was selected as the input for WHU-SGCC blending
167 with rain observations, and the corresponding daily CHIRPS blended data was used for comparisons of precipitation accuracy.

168 The blended in situ daily precipitation observations come from a variety of sources such as: the daily GHCN archive (Durre
169 et al., 2010), the Global Summary of the Day dataset (GSOD) provided by NOAA's National Climatic Data Center, the World
170 Meteorological Organization's Global Telecommunication System (GTS) daily archive provided by NOAA CPC, and over a
171 dozen national and regional meteorological services. The number of daily CHIRP observation stations in the Jinsha River
172 Basin was only 18, compared to the 30 rain gauge stations provided by CMA (Fig. 2).
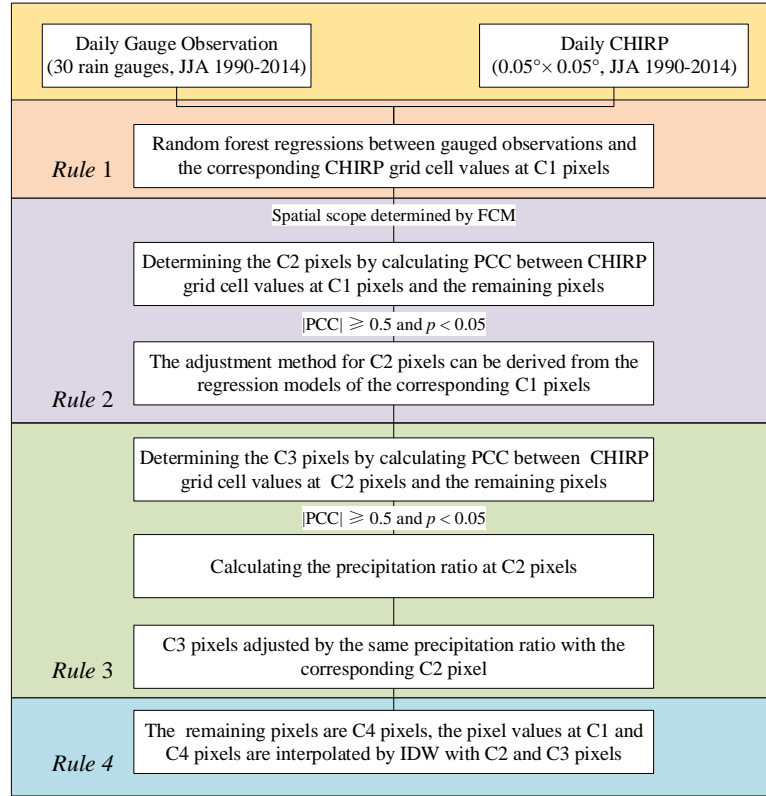

3 Methods

3.1 The WHU-SGCC approach

175 In this study, the approach of the WHU-SGCC is to estimate the precipitation for every pixel by blending satellite estimates
176 and rain gauge observations considering the terrain factors and precipitation characteristics. There were four steps to establish
177 the numerical relationship between gauge stations and the corresponding satellite pixels, and interpolation for the remaining
178 pixels. On this basis, the WHU-SGCC method identifies the geographical locations and topographical features of each pixel
179 and applies the four classification and blending rules. A flowchart of the WHU-SGCC method is shown in Fig. 3. The proposed
180 approach was evaluated over the Jinsha River Basin based on 30 gauge stations and CHIRP satellite-based precipitation
181 estimations during the JJA from 1990 to 2014. The leave-one-out cross validation step was applied to computing the out-of-
182 sample adjusted error with gauge stations.

183 The basic description of the WHU-SGCC method is given below, with details illustrated separately in later sections:

184 1) Classify all regional pixels into four types: C1 (pixel including one gauge station in its area), C2 (pixel statistically similar
185 to C1), C3 (pixel statistically similar to C2) and C4 (remaining pixels).

186   2) Analyse the relationships between precipitation observations and the C1, C2, and C3 pixel types, and with the C4 pixels.

187 These relationships are described by four rules, detailed below as Rules 1 through 4.

188   3) Establish regression models and screen target pixels based on the five aforementioned rules.

189   4) Correct all precipitation pixels in daily regional precipitation images.

190

191

192 **Figure 3** Flowchart of the WHU-SGCC approach with the four rules applied in this study.

3.1.1 Assumptions

194   1) Gauge observations are the most accurate, or "true", values for reference purposes.

195   2) No major terrain change occurred during the twenty years.

196   3) Pearson's Correlation Coefficient (PCC) can indicate the statistically similarity of rainfall characteristics among pixels

197 over a seasonal scale.

3.1.2 Rule 1 of the WHU-SGCC method

199   In general, satellite precipitation estimations deviated from ground-based measurements, which were assumed to be the true

200 values. Rule 1 aims to establish a regression model between each gauge historical observations and the corresponding CHIRP

201 grid cell value. The regression relationship was derived by random forest regression (RFR) at each gauge station. RFR is a

202 machine-learning algorithm for a predictive model with a large set of regression trees in which each tree in the ensemble is

203 grown from a bootstrap (Johnson, 1998) sample drawn with replacement from the training set. The final prediction is obtained

204 by combining the results of the prediction methods applied to each bootstrap sample (Genuer et al., 2017). The predicted value

205 is calculated by the mean of all trees.

$$Y_o = f_{RFR}(Y_s) \tag{1}$$

207   where Y_o denotes each gauge historical observations and Y_s denotes the corresponding CHIRP grid cell values at C1

208 pixels, f_{RFR} is constructed from the time series Y_o (dependent variable) and Y_s (independent variable) by means of RFR.

209 The number of decision trees was set to 500, which was determined by out-of-bag (OOB) error (Figure S1). The OOB error

210 reached the minimum value when the number of decision trees was less than 500.

211 The Rule 1 builds the statistical relationships between gauge observations and corresponding CHIRP grid cell values, which
212 is the key idea in correcting the satellite-based precipitation estimations in the whole study area. As there are 30 gauge stations
213 in the study area, 30 regression relationships at C1 pixels were derived from Rule1. The values of C1 pixels are not corrected
214 in Rule 1, but interpolated in Rule 4.

3.1.3 Rule 2 of the WHU-SGCC method

216 It is reasonable to assume that there are some pixels that are statistically similar to the precipitation characteristics of C1 pixels
217 in a certain spatial scope. Therefore, it is feasible to adjust the satellite estimation bias of C2 pixels by referring to the
218 appropriate regression relationships at corresponding C1 pixels based on Rule 1.

219 First, the spatial scope in which pixels may have highly similar characteristics is established. Some studies indicate that
220 geographical location, elevation and other terrain information influences the spatial distribution of rainfall, especially in
221 mountainous areas with complex topography (Anders et al., 2006;Long and Singh, 2013). The size of the spatial range is an
222 important parameter to distinguish spatial similarity and heterogeneity. In the WHU-SGCC method, the approach of fuzzy c-
223 means (FCM) clustering was explored to determine the spatial range considered as each pixel's terrain factors including
224 longitude, latitude, elevation, slope, aspect and curvature. FCM method was developed by J.C. Dunn in 1973 (Dunn, 1973),
225 and improved in 1983 (Wang, 1983). It is an unsupervised fuzzy clustering method and the steps are as follows (Pessoa et al.,
226 2018):

227 1) Choose the number of clusters c. The optimum number of clusters was determined by $L(c)$ which was derived from the
228 inter-distance and inner-distance of samples in Eq. (2). It is ensured that the distance between the same samples is smaller,
229 while the distance between the different samples is larger.

$$
230 \qquad L(c) = \frac{\sum_{i=1}^{c} \sum_{j=1}^{n} w_{ij}^{m} \| c_i - \bar{x} \|^2 \, /(c-1)}{\sum_{i=1}^{c} \sum_{j=1}^{n} w_{ij}^{m} \| x_j - c_i \|^2 \, /(n-c)} \qquad (2)
$$

231 In Eq. (2), the denominator is inner-distance and the molecular is inter-distance. The initial value of c is 1 and the maximum
232 value of c is the number of gauge stations in this study area. The optimum number of clusters was optimized to maximize the
233 L(c). For this reason, c value is conducted in the range of 1 to the number of gauge stations with an incremental interval value
234 of 1 in this study.

235 2) Assign coefficients randomly to each data point x_i for the degree to which it belongs in the i th cluster $w_{ij}(x_i)$:

$$
237 \qquad c_i^{(t)} = \frac{\sum_{j=1}^{n} w_{ij}^{m} x_i}{\sum_{j=1}^{n} w_{ij}^{m}} \quad (3), \qquad w_{ij} = \frac{1}{\sum_{k=1}^{c} (\frac{\| x_i - c_i \|}{\| x_i - c_k \|})^{\frac{2}{m-1}}} \quad (4), \qquad \bar{x} = \frac{\sum_{i=1}^{c} \sum_{j=1}^{n} w_{ij}^{m} x_j}{n} \quad (5)
$$

239 where x is a finite collection of n elements that will be partitioned into a collection of c fuzzy clusters, c_i is the centre of

240 each cluster, m is the hyper-parameter that controls the level of cluster fuzziness and w_{ij} is the degree to which element x_i

241 belongs to c_i and $\bar{x}$ is the center vector of collection. In Eq. (3), $c_j^{(t)}$ represents the cluster centre in iteration t. If the

242 minimum improvement in objective function between two consecutive iterations satisfies the following equation, the algorithm

terminates in iteration t (Eq. (6)):

$$\|c_i^{(t)} - c_i^{(t+1)}\| < \varepsilon \tag{6}$$

3) Minimize the objective function F_c to achieve data partitioning.

$$F_c = \sum_{j=1}^{n} \sum_{i=1}^{c} w_{ij}^{m} \| x_j - c_i \|^2 \tag{7}$$

The results of FCM are the degree of membership of each pixel to the cluster centre as represented by numerical value. Pixels in each cluster have similar terrain features and precipitation characteristics.

Second, as mentioned above, the aim of Rule 2 is to derive an adjustment method for C2 pixels based on learning from Rule 1. With the establishment of a regression relationship between gauge observations and the corresponding CHIRP grid cell values of the C1 pixels by RFR method, the determination of C2 pixels follows a considerable procedure. With exception of the C1 pixels, the remaining pixels in each cluster represent potential C2 pixels called R pixels. Pearson's correlation coefficient (PCC) and p-values between the satellite estimations (CHIRP grid cell values) at R pixels and the C1 pixels are the criteria for final determination of C2 pixels. The PCC is defined as follows:

$$PCC_{x,y} = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2}\sqrt{\sum_{i=1}^{n}(y_i - \bar{y})^2}} \tag{8}$$

where n is the number of samples, x_i and y_i are individual samples (CHIRP grid cell values at C1 and C2 pixels), $\bar{x}$ is the arithmetic mean of x calculated by $\bar{x} = \frac{1}{n}\sum_{i=1}^{n} x_i$, $\bar{y}$ is the arithmetic mean of y calculated by $\bar{y} = \frac{1}{n}\sum_{i=1}^{n} y_i$.

The value range of the PCC is between -1 and +1. If there are no repeated data values, a perfect PCC of +1 or −1 occurs when each of the variables is a perfect monotone function of the other. However, if the value is close to zero, there is zero correlation. In addition, correlation is not only determined by the value of the correlation coefficient but also from the correlation test's p-value. The critical values for PCC and p-value are 0.5 and 0.05, thus a PCC value higher than 0.5 and a p-value lower than 0.05 indicate the data are significantly correlated (Zhang and Chen, 2016). Therefore, the final determination of C2 pixels must meet the following criteria:

$$|PCC| \geq 0.5 \quad and \quad p < 0.05 \tag{9}$$

Each R pixel has m PCC and p-values (the number of C1 pixels in the cluster), and the subset of C2 pixels is identified by excluding the data that failed the correlation test and retaining both the data with a maximum PCC of at least 0.5 and a p-value lower than 0.05, and the corresponding index of C1 pixels. The selected C2 pixels are statistically similar to the precipitation characteristics of corresponding C1 pixels in their defined spatial scope.

After identifying the C2 pixels and their corresponding C1 pixels, the adjustment method for C2 pixels is derived from the regression model for the C1 pixels.

$$C2_{as} = f_{RFRc}(Y_s) \tag{10}$$

where $C2_{as}$ is the adjusted satellite precipitation estimate and Y_s is the CHIRP grid cell value at the C2 pixels, and f_{RFRc} is the f_{RFR} of corresponding C1 pixel.

3.1.4 Rule 3 of the WHU-SGCC method

Recognizing that precipitation has a spatial distribution, the assumption that C3 pixels are statistically similar to the precipitation characteristics of C2 pixels is adopted to establish the adjustment method for C3 pixels.

First, the determination of C3 pixels in each spatial cluster is based on the selection of C2 pixels. The satellite-based estimation values at the remaining pixels with exception of the C1and C2 pixels are used to calculate the PCC and p-value with the satellite-based estimation values at the C2 pixels in the same cluster. The results of each pixel's k PCC and p-value (the number of C2 pixels in the cluster) are evaluated based on the correlation test (Eq. (9)) that the pixels with a maximum PCC of is at least 0.5, and then the corresponding index of C2 pixels are retained. The selected pixels called C3 pixels, which are statistically similar to the precipitation characteristics of the corresponding C2 pixels in the defined spatial scope.

After identifying the C3 pixels, a method for merging the CHIRP grid cell values at C3 pixels (Y_s) and the target reference values of $C2_{as}$ at the corresponding C2 pixels is applied to estimate the adjusted precipitation values at C3 pixels. This method combines Y_s and $C2_{as}$ values in one variable, as shown in Eq. (11):

$$w_i = \frac{C2_{as_i} + \lambda}{Y_{s_i} + \lambda} \quad i=1,\ldots,\ n \tag{11}$$

where λ is a positive constant set to 10 mm (Sokol, 2003), $C2_{as}$ is the adjusted precipitation values at the C2 pixels, Y_{s_i} is extracted from the CHIRP grid cell values at the corresponding location of the C2 pixel, and n is the number of C2 pixels in each spatial cluster.

Each w of the C3 pixels is assigned the same value as the corresponding C2 pixel. Therefore, the values of C3 pixels are derived from Eq. (12):

$$C3_{as} = \max(w \times (Y_s + \lambda) - \lambda, 0) \tag{12}$$

where $C3_{as}$ is the adjusted target precipitation value at one C3 pixel and Y_s is the corresponding CHIRP grid cell value. To avoid precipitation estimates below 0, Eq. (12) sets these negative values to 0.

3.1.5 Rule 4 of the WHU-SGCC method

Excluding the C1C2and C3 pixels, the number of remaining pixels, called C4 pixels which are adjusted by Inverse Distance Weighted (IDW). IDW is based on the concept of the first law of geography from 1970. It was defined as e*verything is related to everything else, but near things are more related than distant things*. Therefore, the attribute value of an unsampled point is the weighted average of known values within the neighbourhood and the distance weighting can be determined by IDW (Lu and Wong, 2008). In Rule 4, IDW is used to interpolate the unknown spatial precipitation data from the C2 and C3 pixels adjusted precipitation values. The IDW formulas are given as Eq. (13) and Eq. (14).

$$R_{as} = \sum_{i=1}^{n} w_i R_i \tag{13}$$

$$w_i = \frac{d_i^{-\alpha}}{\sum_{i=1}^{n} d_i^{-\alpha}} \quad \text{with} \quad \sum_{i=1}^{n} w_i = 1 \tag{14}$$

where R_{as} is the unknown spatial precipitation data, R_i is the adjusted precipitation values at C2 and C3 pixels, n is the number of C2 and C3 pixels, d_i is the distance from each C2 or C3 pixel to be unknown grid cell, α is the power which is generally specified as a geometric form for the weight. Several researches (e.g., Simanton and Osborn 1980; Tung 1983) have experimented with variations in a power, the small α tends to estimate values with the averages of sampled grids in the neighbourhood, while large α tends to give larger weights to the nearest points and increasingly down-weights points farther away (Chen and Liu, 2012;Lu and Wong, 2008). The value of α has an influence on the spatial distribution of information from precipitation observations. For this reason, α value is conducted in the range of 0.1 to three (0.1, 0.3, 0.5, 1.0, 1.5, 2.0,

312   2.5 and 3.0) in this study.

313   It is noted that the unknown spatial precipitation data including C1 and C4 pixels, because C1 pixels values were not adjusted

314   in Rule 1.

315   In the end, after applying these four rules, we obtained complete daily adjusted regional precipitation maps for the summer

316   (JJA) over the Jinsha River basin.

317   **3.2 Accuracy assessment**

318   The performance of the WHU-SGCC adjusted precipitation estimates was evaluated by nine statistical indicators: Pearson's

319   correlation coefficient (PCC), root mean square error (RMSE), mean absolute error (MAE), relative bias (BIAS), the Nash-

320   Sutcliffe efficiency coefficient (NSE), probability of detection (POD) and false alarm ratio (FAR) and critical success index

321   (CSI). PCC, RMSE, MAE and BIAS were used to evaluate how well the WHU-SGCC method adjusted satellite estimation

322   bias, while POD, FAR and CSI were used to evaluate the precipitation event predictions (Su et al., 2011). PCC measures

323   strength of the correlation relationship between the satellite estimations and observations. MAE represents the average

324   magnitude of error estimations, considering both systematic and random errors. The NSE (Nash and Sutcliffe, 1970)

325   determines the relative magnitude of the variance of the residuals compared to the variance of the observations, bounded by

326   minus infinity to 1. A negative value indicates a poor precipitation estimate and the value of an optimal estimate is equal to 1.

327   BIAS measures the mean tendency of the estimated precipitation to be larger (positive values) or smaller (negative values)

328   than the observed precipitation, with an optimal value of 0.

329   POD, also known as the hit rate, represents the probability of rainfall detection. FAR is defined as the ratio of the false

330   detection of rainfall to the total number of rainfall events. All of the accuracy assessment indices are shown in Table 3.

331

Table 3 Accuracy assessment indices.

Accuracy assessment Index	Unit	Formula	Range	Optimal value
Pearson's Correlation Coefficient (*SCC*)	NA	$SCC = \dfrac{\sum_{i=1}^{n}(Y_{oi} - \bar{Y}_o)(C_i - \bar{C})}{\sqrt{\sum_{i=1}^{n}(Y_{oi} - \bar{Y}_o)^2} \cdot \sqrt{\sum_{i=1}^{n}(C_i - \bar{C})^2}}$	[-1,1]	1
Root Mean Square Error (RMSE)	Mm	$RMSE = \sqrt{\dfrac{1}{n-1}\sum_{i=1}^{n}(C_i - Y_{oi})^2}$	[0,+∞）	0
Mean Absolute Error (MAE)	Mm	$MAE = \dfrac{1}{n}\sum_{i=1}^{n}|C_i - Y_{oi}|$	[0, +∞)	0
Relative Bias (BIAS)	NA	$BIAS = \dfrac{\sum_{i=1}^{n}(C_i - Y_{oi})}{\sum_{i=1}^{n} Y_{oi}}$	(-∞, +∞)	0
Nash-Sutcliffe Efficiency Coefficient (*NSE*)	NA	$NSE = 1 - \dfrac{\sum_{i=1}^{N}(C_i - Y_{oi})^2}{\sum_{i=1}^{N}(C_i - \bar{Y}_o)^2}$	(-∞,1]	1
Probability of Detection (POD)	NA	$POD=H/(H+M)$	[0,1]	1
False Alarm Ratio (FAR)	NA	$FAR=F/(H+F)$	[0,1]	0
Critical Success Index (CSI)	NA	$CSI=H/(H+M+F)$	[0,1]	1

332   Note: Y_{oi} is the observation data and C_i is the adjusted value using the WHU-SGCC method for test sample pixel; $\bar{Y}_o$ is

333   the arithmetic mean of Y_o and is given by $\bar{Y}_o = \dfrac{1}{n}\sum_{i=1}^{n} Y_{oi}$; $\bar{C}$ is the arithmetic mean of C and is given by $\bar{C} = \dfrac{1}{n}\sum_{i=1}^{n} C_i$;

334   H represents the number of both observed and estimated precipitation events (successfully forecasted), and F is the number of

335   false alarms when observed precipitation was below the threshold and estimated precipitation was above threshold (false

336   alarms). M is the number of events in which the estimated precipitation was below the threshold and observed precipitation

337   was above the threshold (missed forecasts). POD and FAR values are dimensionless numbers ranging from 0 to 1. The

338   precipitation threshold (event/no event) was set to 0.1 mm/day.

4 Results and Discussion

There were 18482 daily pixels adjusted by blending satellite estimations (CHIRP) and observations (gauge stations and gridded points) using the WHU-SGCC approach during the JJA from 1990 to 2014. The number of pixels adjusted by each rule in the WHU-SGCC method is shown in Table 4. The number of C1 pixels was the number of training gauge stations accounting 0.16% of the total pixels (18482) inside the basin. Due to the leave-one-out cross validation step, the different training samples will have the different number of C2, C3 and C4 pixels respectively inside the Jinsha River Basin. The number of C4 pixels was approximately 10822 with the percentage around 60%, the number of C3 pixels was approximately 4331 with the percentage ranging from 21.72% to 24.40%, and the number of C2 pixels was approximately 3300 with the percentage ranging from 15.59% to 18.36%.

Table 4 The number of each class pixels adjusted by each rule using the WHU-SGCC method inside the Jinsha River Basin.
Validation gauge station	C1 Pixels (%)	C2 Pixels (%)	C3 Pixels (%)	C4 Pixels (%)

4.1 Spatial Clustering from the FCM method

To adjust the pixels other than for the gauged stations, the pixels statistically similar to the C1 were selected. According to Rule 2, C2 pixels were identified in a spatial scope defined by the FCM method. In the following experiments of Rule 2, we set the parameters $m=2, \varepsilon=0.00001$ and the maximum number of iterations was set 1000 (an enough large value with the consideration of the algorithm efficiency). In order to determine the optimal numbers of clusters, c value was conducted in the
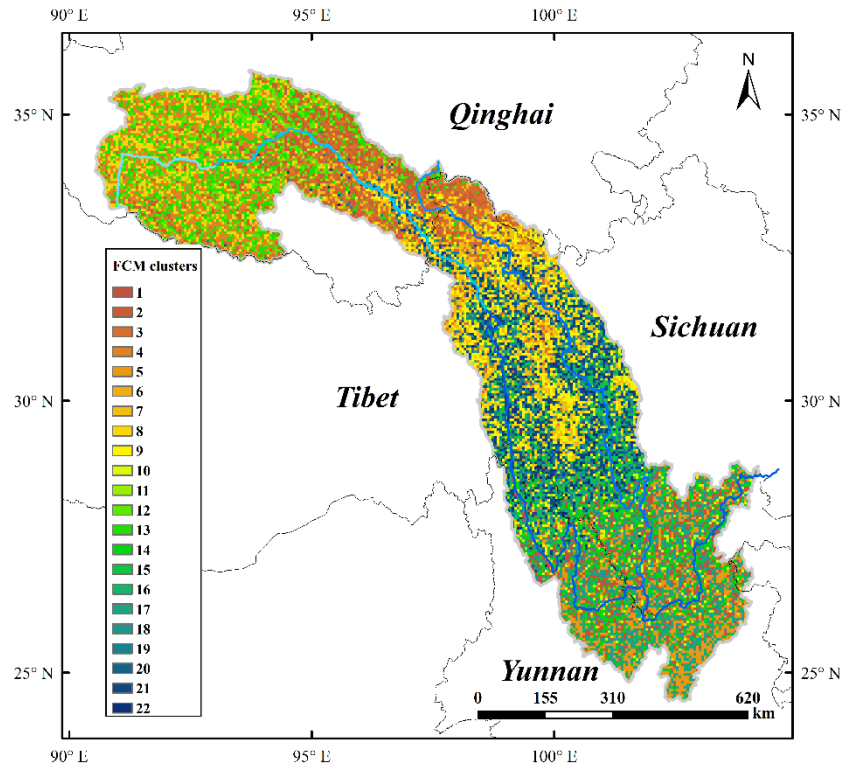

12

range from 1 to 30 with an incremental interval value of 1 in this study. During the running of FCM approach, the values of $L(c)$ were shown in Fig 4. Figure 4 shows the optimum number of clusters was 22, with the number of iterations was 690 less than the maximum number of iterations.

Figure 4 The optimum number of clusters determined by the maximum $L(c)$ with the iterative process.

Therefore, the number of clusters was set to 22 and the number of iterations was still set to 1000 for fully operations by means of FCM. The spatial clusters results with consideration of the terrain factors was shown in Fig. 5. Overall, the spatial results of FCM have many of the same characteristics as spatial areas defined by terrain changes, especially with respect to slope and runoff directions, which may influence regional rainfall to some extent.

Figure 5 Spatial clustering as defined by FCM for the Jinsha River Basin.

4.2 Model performance based on overall accuracy evaluations

To test the performance of the WHU-SGCC method for precipitation estimates, the statistical analyses of PCC, RMSE, BAE, BIAS, NSE, POD, FAR, and CSI were calculated and are presented in Table 5 (The results were derived from the $\alpha = 0.1$ for
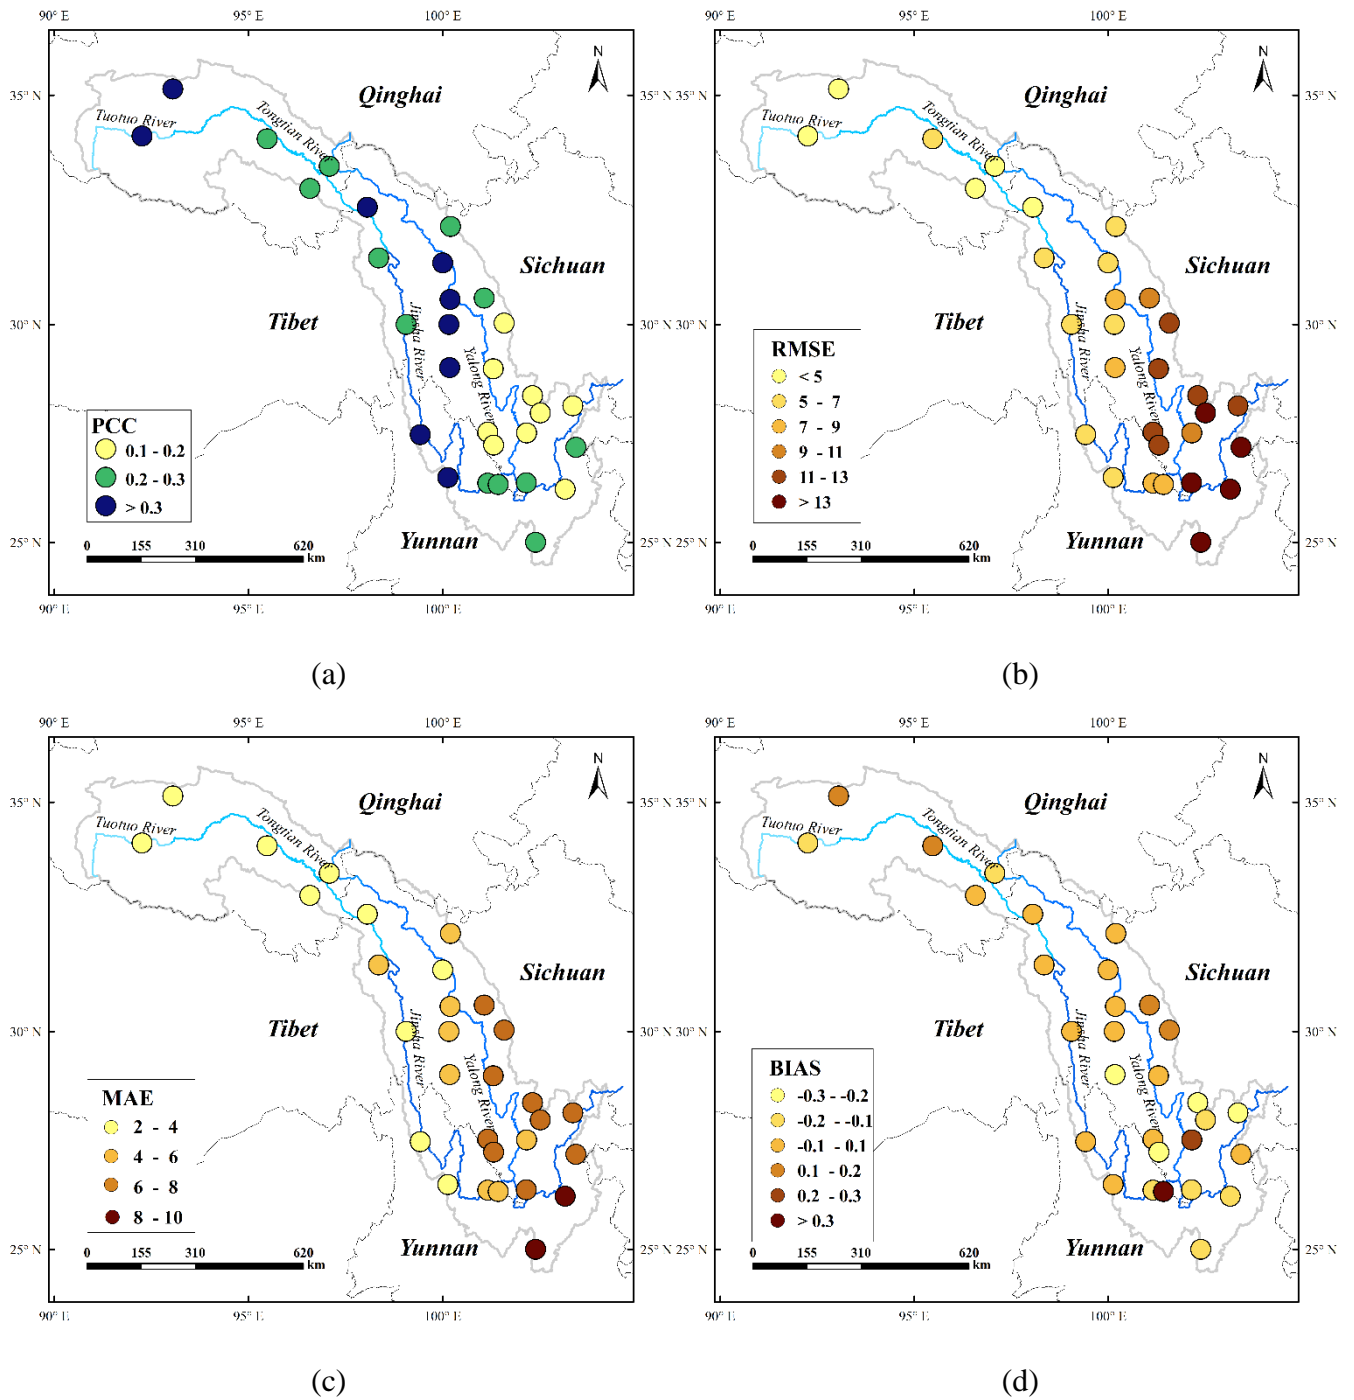

13

IDW in Rule 4 with the comparison with other values in RMSEs). Compared with the satellite images of CHIRP and CHIRPS, the results of the WHU-SGCC provide the greatest improvements for regional daily precipitation estimates over the Jinsha River Basin during JJA from 1990 to 2014. After bias adjustment of the WHU-SGCC, PCC was improved by 3.34% and 31.81% compared to CHIRP and CHIRPS, respectively. Meanwhile, the RMSE and MAE of the WHU-SGCC decreased by 6.91% and 6.59% compared to CHIRP, and by 22.71% and 22.15% compared to CHIRPS. Although, the absolute value of BIAS of WHU-SGCC was no significant improvement than CHIRP and slightly higher than CHIRPS, all of the values were approximately to 0. This results of BIAS indicates that the all three kinds of data were much the same on the performance. Nevertheless, the NSE of the WHU-SGCC reached -0.0137, an increase of 93.33% and 98.32% compared to CHIRP and CHIRPS, respectively. The NSE of WHU-SGCC was still far less than 1, but it was improved to be zero that indicates the adjusted results are close to the average level of the rain gauge observations, while the NSEs of CHIRP and CHIRPS were much worse. It is noted that the POD of WHU-SGCC was approximate to 1, better than CHIRP and CHIRPS, and the FAR of WHU-SGCC was 0.11, lower than CHIRP and CHIRPS, which represents the better ability on precipitation event predictions of the WHU-SGCC.

Table 5 Overall accuracy assessment during the JJA from 1990 to 2014.

Statistic	WHU-SGCC	CHIRP	CHIRPS
PCC	0.2536	0.2454	0.1924
RMSE	8.7608	9.4108	11.3354
MAE	5.4564	5.8415	7.0088
BIAS	-0.0167	-0.0443	-0.0134
NSE	-0.0139	-0.2083	-0.8293
POD	0.9932	0.9578	0.4351
FAR	0.1146	0.2323	0.1601
CSI	0.8799	0.7405	0.4010

4.3 Model performance based on the spatial distributions

The spatial distributions of the statistical comparisons between observations and WHU-SGCC precipitation estimations are shown in Fig. 6. The variation of PCC as seen in Fig. 6 (a) shows that low correlations are observed in areas with lower elevation, particularly in the southern Jinsha River Basin where there is higher precipitation and a greater density of rain gauges. This result is in contrast to the result in (Rivera et al., 2018), because of the few days for heavy rains in this study area. The higher correlations noted over the north central area of the river basin are in a drier region with complex terrain and sparse rain gauges. With respect to the spatial distribution of RMSE, Fig. 6 (b) indicates that smaller errors are scattered in the northwest area of the river basin, with values lower than 5 mm, while the highest errors, which are over 10 mm, are located over the border between the lower reaches of the Jinsha Jiang River and the river basin. All the values of MAE are below 10 mm and the spatial behaviour is similar to that of the RMSE. Fig. 6 (c) shows that the lower MAE values are located over the mountainous region southwest of Qinghai and west of Sichuan, with values below 6 mm. The spatial distribution of the BIAS indicates that the WHU-SGCC has good agreement with the observations, with the most values ranging from -10%~10%. All the spatial distribution statistics indicate that the statistical relationships established during the process of the WHU-SGCC method is susceptible to the mode values of the rain gauge stations data. Although the average annual precipitation in the southern Jinsha River Basin was more than 600 mm (Fig.2), the days of light rain were still in the great percentage that limited the performance over the south area, while there were sufficient data with similar precipitation features for WHU-SGCC over the north data. Nevertheless, WHU-SGCC approach is still effective in adjusting the satellite biases by blending with the observations, particularly in the complicated mountainous region where there are higher PCC corresponding to lower values of RMSE, MAE and BIAS.

407 error, and d) relative bias.

408 **4.4 Model performance for rain events**

409 To measure the WHU-SGCC performance for different rain events, the daily precipitation thresholds of 0.1, 10, 25, and 50mm

410 were considered, and the result is shown in Table 6 and Table 7. The days of each class of rain events at the validation gauge

411 station during JJA from 1990 to 2014 were shown in Table 5. The major rain events inside the Jinsha River Basin were light

412 rain (0.1-10 mm), accounting for 54.76% of the total days (the average percentage of rain event days in its total days at each

413 gauge station), while the days with daily precipitation over the 50 mm was least, only accounting for 0.72%. And the percentage

414 of the daily precipitation of <0.1, 10-25, and 25-50 mm were 26.89%, 14.01% and 3.62% respectively. The result indicated

415 that the average daily precipitation was less than 10 mm, though in the summer seasons during the multi-year. As well as, the

416 spatial distribution of precipitation was also uneven, with an increase from north to south.

56671	616	886	289	148	70	2009
56684	768	899	246	114	19	2046
56778	682	930	274	119	43	2048

418   In terms of performance with respect to different daily rain events, the WHU-SGCC approach had the lowest error, as
419 indicated by RMSE, MAE and BIAS for events with total rainfall lower than 25 mm, but WHU-SGCC performance for total
420 rainfall higher than 25 mm did not improve compared to CHIRP and CHIRPS (Table 6). This negative performance on the
421 total rainfall higher than 25 mm was probably caused by the precipitation conditions inside the Jinsha River Basin (Table 5).
422 The average daily precipitation was less than 10 mm inside the basin, during the multi-year summer seasons, which provided
423 a large amount of rain gauge stations data with the values lower than 10 mm, that caused a significantly impact on the statistical
424 relationships establishment for WHU-SGCC. In hence, the approach of WHU-SGCC is applicable for the detection of rainfall
425 events over the Jinsha River Basin, with the precipitation less than 10 mm, or even than 25mm. Due to the 4.34% of summer
426 days with the daily precipitation over the 25 mm, the performance of WHU-SGCC on these rain events was poorer than the
427 results of CHIRP and CHRPS.

5 Conclusions

This study provided a novel approach in the WHU-SGCC method for merging daily satellite-based precipitation estimates with observations. A case study of Jinsha River Basin was conducted to verify the effectiveness of the WHU-SGCC approach during the JJA from 1990 to 2014, and the adjusted precipitation estimates were compared to CHIRP and CHIRPS. WHU-SGCC aims to reduce systematic and random errors in CHIRP over a region that has complicated mountainous terrain and sparse rain gauges. To the best of the authors' knowledge, this study is the first to use daily CHIRP and CHIRPS data in this area.

According to our findings, the following conclusions can be drawn: (1) The WHU-SGCC method is effective for the adjustment of precipitation biases from point to surface. The precipitation estimated by the WHU-SGCC method can achieve greater accuracy, which was evaluated with PCC, RMSE, MAE, BIAS, NSE, POD, FAR and CSI. Particularly, the NSE statistic was improved by 93.33% and 98.32% compared to CHIRP and CHIRPS, respectively, and all measured errors were reduced except the BIAS with no significant improvement, but approximately to 0. The results show that compared to CHIRPS, the WHU-SGCC approach can achieve substantial improvements in precipitation estimate accuracy. (2) Moreover, the spatial distribution of precipitation estimate accuracy derived from the WHU-SGCC method is related to the complexity of the topography. These random errors over the lower evaluations and the large size of light precipitation events with short duration rainstorms in the region resulted in a limited improvement in accuracy, with PCC values less than 0.3, However, higher PCC and lower errors were observed over the north central area of the river basin, which is a drier region with complex terrain and sparse rain gauges. All the spatial distribution statistics indicate that the WHU-SGCC method is superior for adjustment of satellite biases by blending with the observations over the complex terrain region. (3) The WHU-SGCC validations for daily rain events confirmed that the model was effective in the detection of precipitation events less than 25 mm due to the less average annual precipitation inside the Jinsha River Basin. According to the comparison, the WHU-SGCC approach achieves error reductions for the RMSE, MAE and BIAS statistics for rain events within the range of 1-25 mm. Specifically, compared with CHIRP, the RMSE value was reduced by approximately by 5.92%-39.44%, the MAE value by 4.28%-12.41%, and the absolute BIAS value by 9.15%-44.43%; compared with CHIRPS, the RMSE and MAE values were reduced by 11.04%-56.61%, and the absolute BIAS value by 23.77%-59.58%.

Therefore, the WHU-SGCC approach can help adjust the biases of daily satellite-based precipitation estimates over the Jinsha River Basin, the complicated mountainous terrains with sparse rain gauges, particularly for precipitation events with less than 25 mm in summer. This approach is a promising tool to monitor monsoon precipitation over the Jinsha River Basin, considering the spatial correlation and historical precipitation characteristics between raster pixels located in regions with similar topographic features. Future development of the WHU-SGCC approach will focus on the following three aspects: 1) improvement of the adjusted precipitation quality by blending in different rain events and applying in all seasons; 2) introduction of more topographic factors and climatic factors to achieve a more accurate spatial distribution of precipitation;

465   and 3) investigation of the performance over other areas and on the particular hydrological case to validate the WHU-SGCC.
